1.) Printf uses %f and scanf use %lf they differ because the wrong specifier for these can result in different issues and must match the argument.

2.) One outputs 3 while the other outputs 3.50000. This is because the difference in integer and double division. Where one rounds and the other doesn't so our results differ.

3.) Scanf will return the input items successfully converted and assigned equal to the requested amount, if the first fails however, it returns a 0 from not matching the format, where otherwise a 1 is returned.

4.) X will remain the same value from failure to convert. In the input stream the ‘abc’ remains due to the character not being valid so it remains in the input.

5.) conversion should return double due to the nature of rounding and how often these conversions leave decimal values which can be lost without the precision of double. We receive greater accuracy more frequently this way.
